

P1. Sketch the curves parameterised by

(a)  $\mathbf{r}(t) = (t^2, t^3)$ ,  $t \in \mathbb{R}$ ;

(b)  $\mathbf{r}(t) = t \cos t \mathbf{i} + |t| \sin t \mathbf{j}$ ,  $t \in \mathbb{R}$ ;

(c)  $\mathbf{r}(t) = \frac{1+e^{-t}}{1+2e^{-t}} (\cos t, -\sin t)$ ,  $t \in \mathbb{R}$ ;

(d)  $\mathbf{r}(t) = \cos(t) \mathbf{i} + \sin(t) \mathbf{j} + t^2 \mathbf{k}$ ,  $t \in \mathbb{R}$ .

In cases where you cannot show the whole curve, just show a representative portion. Use arrows to indicate the direction in which  $t$  increases. These sketches must be accompanied by brief explanations (and a few words/calculations) justifying their shapes; For each curve state, with justification, whether or not it is embedded and whether or not it is closed.

a.)  $\mathbf{r}(t) = (t^2, t^3)$ ,  $t \in \mathbb{R}$ ;

We can use the graph of the function  $f: \mathbb{R} \rightarrow \mathbb{R}$ ,  $f(x) = x^3/2$  for  $x \geq 0$ .

And the function  $g: \mathbb{R} \rightarrow \mathbb{R}$ ,  $g(x) = -x^3/2$  for  $x < 0$ .

A curve is **embedded** if it doesn't have self-intersecting points. We can also use the fact that  $\mathbf{r}(t)$  is injective to prove that it is embedded.

Let  $t_1, t_2$  be real numbers such that  $t_1 \neq t_2$ . Suppose that  $\mathbf{r}(t_1) = \mathbf{r}(t_2) \Rightarrow$

$(t_1^2, t_1^3) = (t_2^2, t_2^3) \Rightarrow t_1^2 = t_2^2$  and  $t_1^3 = t_2^3$  have to be true at the same time,

which can only happen if  $t_1 = t_2$ . So we have a contradiction and  $\mathbf{r}(t)$  is injective, therefore the curve is embedded.

A curve is **closed** if its endpoints meet. In our case the endpoints are  $-\infty$  and  $\infty$ , which never meet, so the curve is **not closed**.

b.)  $r(t) = t\cos(t)\mathbf{i} + |t|\sin(t)\mathbf{j}$ ,  $t \in \mathbb{R}$ .

We have  $x = t\cos(t)$  and  $y = |t|\sin(t)$ . We notice that if we square these two equations and add them together, we get the equation of a circle with radius  $t$ , where the radius is changing:

$$x^2 + y^2 = t^2$$

So as  $t$  increases or decreases, the circles get smaller or larger, and we will have a spiral.

<https://www.desmos.com/calculator/22e4dvyezx>

Now similarly to a.), we have to prove that the function  $r(t) = t\cos(t)\mathbf{i} + |t|\sin(t)\mathbf{j}$ , which also means that the curve is **embedded**.

Let's assume that  $r(t_1) = r(t_2)$ . So we have  $t_1\cos(t_1) = t_2\cos(t_2)$  and  $|t_1|\sin(t_1) = |t_2|\sin(t_2)$  at the same time.

We get  $t_1 = t_2\cos(t_2)/\cos(t_1)$ , which implies that  $t_1 = t_2$ . Thus  $r(t_1) = r(t_2)$  only if  $t_1 = t_2$ , which means the function is injective.

Because the spiral keeps growing and approaching infinity, we **do not have a closed curve**.

c.)  $r(t) = (1+e^{-t})/(1+2e^{-t})(\cos t, -\sin t)$ ,  $t \in \mathbb{R}$ .

We have the parametric equations:  $x = (1+e^{-t})/(1+2e^{-t})\cos t$  and  $y = (1+e^{-t})/(1+2e^{-t})(-\sin t)$ .

Again by squaring them and adding them up we get an equation similar to that of a circle, where the radius  $R = (1+e^{-t})/(1+2e^{-t})$  depends on  $t$ .

<https://www.desmos.com/calculator/wywlazmjib>

This curve is also **embedded**. Suppose that  $t_1 \neq t_2$ , but  $r(t_1) = r(t_2)$ . This is equivalent to proving that the function  $f(t) = \frac{(1+e^{-t})}{(1+2e^{-t})}$  is injective. So we have  $\frac{(1+e^{-t_1})}{(1+2e^{-t_1})} = \frac{(1+e^{-t_2})}{(1+2e^{-t_2})}$ . After some basic computations we get  $e^{-t_1} + 2e^{-t_2} = e^{-t_2} + 2e^{-t_1} \Rightarrow e^{-t_1} = e^{-t_2}$ , and we know that the exponential function is bijective.

This curve **isn't closed** either as the two endpoints don't meet.

d.)  $r(t) = \cos(t)\mathbf{i} + \sin(t)\mathbf{j} + t^2\mathbf{k}$ ,  $t \in \mathbb{R}$ .

We have the parametric equations  $x = \cos t$ ,  $y = \sin t$  and  $z = t^2$ .

<https://www.geogebra.org/calculator/nvayem8z>

The curve is **not embedded** because it has self-intersection points which we can find.

Let  $t_1 = \pm t_2$ , we show that  $r(t_1)$  can be equal to  $r(t_2)$ , with the property that  $t_1^2 = t_2^2$ ,  $\cos(t_1) = \cos(t_2)$  and  $\sin(t_1) = \sin(t_2)$ .

From  $t_1^2 = t_2^2$  we have  $t_1 = \pm t_2$ .

$\cos(-t_2) = \cos(t_2)$  is true because it is an even function.

$\sin(t_1) = \sin(t_2)$  is only true if it is equal to 0. So  $t = k\pi$ ,  $k \in \mathbb{Z}$ , are the points where the curve self-intersects.

Just like the rest, this curve also **isn't closed**, even though it has self-intersection points, it never 'stops', but the two endpoints keep approaching infinity along the Oz axis.
